Prokaryotic communities from a lava tube cave in La Palma Island (Spain) are involved in the biogeochemical cycle of major elements

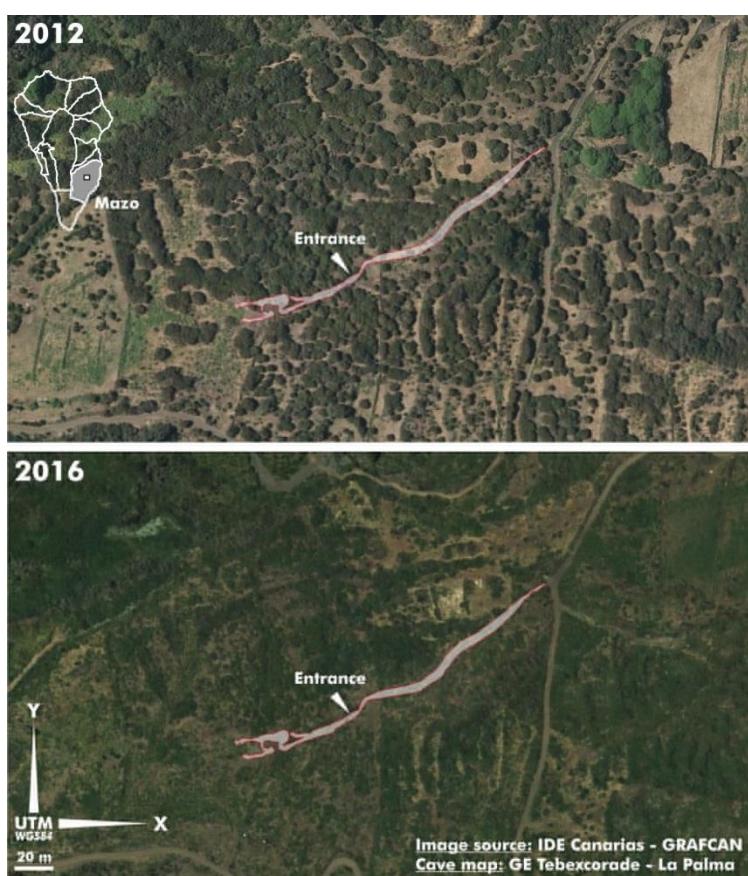

Jose Luis Gonzalez-Pimentel¹, Tamara Martin-Pozas², Valme Jurado³, Ana Zelia Miller¹, Ana Teresa Caldeira¹, Octavio Fernandez-Lorenzo⁴, Sergio Sanchez-Moral² and Cesareo Saiz-Jimenez³

⁴Grupo de Espeleología Tebexcorade, La Palma, Spain

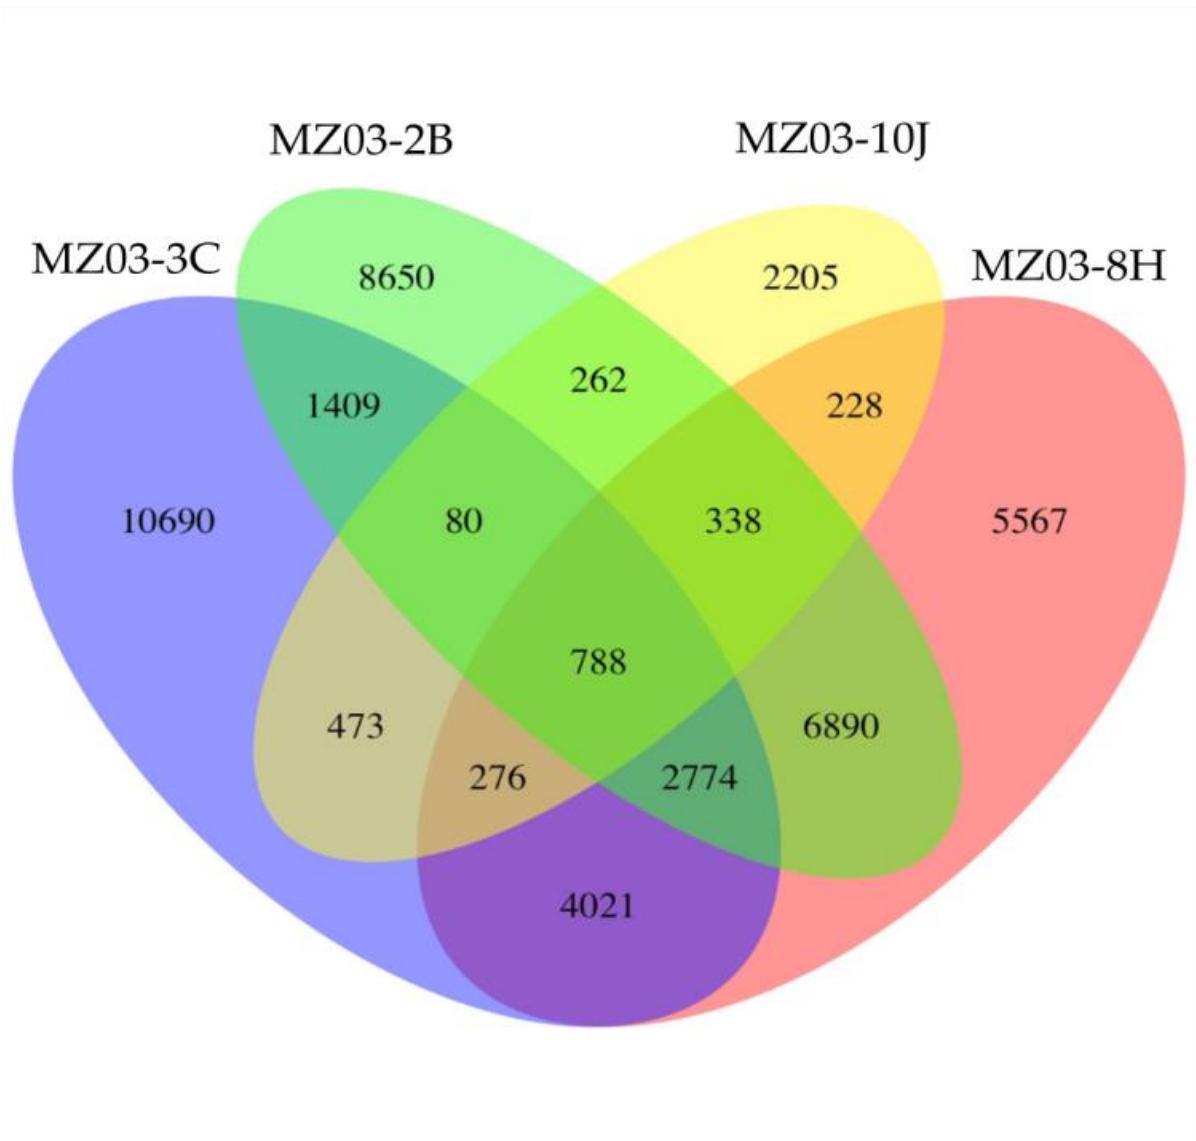

Supplemental Figure 1. Aerial photos of the cave area before the August 4, 2012 fire, and in 2016.

Fuente de la Canaria Cave opens its entrance on a midland slope facing east-southeast, which shows terraces dedicated to rainfed crops, today abandoned, and totally or partially occupied by forage plants, mainly *Chamaecytisus prolifer* subsp. *prolifer* var. *palmensis*, known locally as tagasaste palmero. The vegetation of the area was the evergreen laurel cloud forest with abundance of the wax

myrtle *Myrica faya* and the shrubby *Erica arborea* (tree heath), community known as monteverde or fayal-brezal. The entire area was devastated by a fire in 2012 affecting the surface vegetation and most heaths have been reduced to stumps that, in some cases, are sprouting again from the roots (Supplementary Fig. S1). There are still some specimens in the vicinity of the cave, particularly *Erica arborea*, a species of which one specimen is growing at the cave entrance. Tagasastes are currently the most abundant species. Small herds of cows occasionally graze on the soil above the cave.

Supplemental Figure 2. Sampling in Fuente de la Canaria Cave. White stains on the walls correspond to the area of moonmilk (MZ03-10J).

Supplemental Figure 3. Venn diagram at a distance of 0.03 of the shared OTUs among samples MZ03-3C (20511), MZ03-2B (21191), MZ03-8H (20882) and MZ03-10J (4650).

Supplemental Table 1. Selection of enzymes related to methane metabolism. The EC number abundance predicted by PICRUSt2 show how each dominant taxon is contributing to each predicted enzyme per sample.
